Slide Credits: P. Duygulu Sahin, T. Darrell, M. Black, M. Hebert, R. Owens, D. Forsyth, and J. Ponce

Motion

- A lot of information can be extracted from time varying sequences of images, often more easily than from static images.
  - e.g, camouflaged objects are only easily seen when they move.
  - the relative sizes and position of objects are more easily determined when the objects move.

- For example, given an image of a moving car, deciding which pixels in the image represent motion can help to decide which pixels belong to the car, and which to the static background.

Adapted from Robyn Owens, http://homepages.inf.ed.ac.uk/rbf/CVonline/LOCAL_COPIES/OWENS/LECT12/node3.html

Biological Motivation for Studying Motion

- Estimation of the motion of predators advancing at a mobile animal is important to its ability to take flight away from the predator and survive
- Human beings do it all the time without even realizing it, for example, this is why we have saccadic eye movements (that is our eyes jump from focusing at one spot to another). Thus, if the scene has no motion, our eyes are moving.
- Fixating on something close and very far away and moving your head (either sideways or forward and backward), you can notice that the retinal image of the close tree moves more than the one of a distant tree, i.e. the motion in the retinal plane is inversely proportional to the distance from the retinal plane.
- Animals obtain some information about the environment structure, e.g. pigeons move their necks to get the so called ``motion parallax''.

Adapted from Kosecka & Sastry

Motion

- Studying the motion in detail, we can answer such questions as
  - How many moving objects there are?
  - Which directions they are moving in?
  - Whether they are undergoing linear or rotational motion?
  - How fast they are moving?

Adapted from Robyn Owens, http://homepages.inf.ed.ac.uk/rbf/CVonline/LOCAL_COPIES/OWENS/LECT12/node3.html

Motion

- The analysis of visual motion consists of two stages:
  - the measurement of the motion,
  - the use of motion data to segment the scene into distinct objects and to extract three dimensional information about the shape and motion of the objects.

Adapted from Robyn Owens, http://homepages.inf.ed.ac.uk/rbf/CVonline/LOCAL_COPIES/OWENS/LECT12/node3.html

Motion

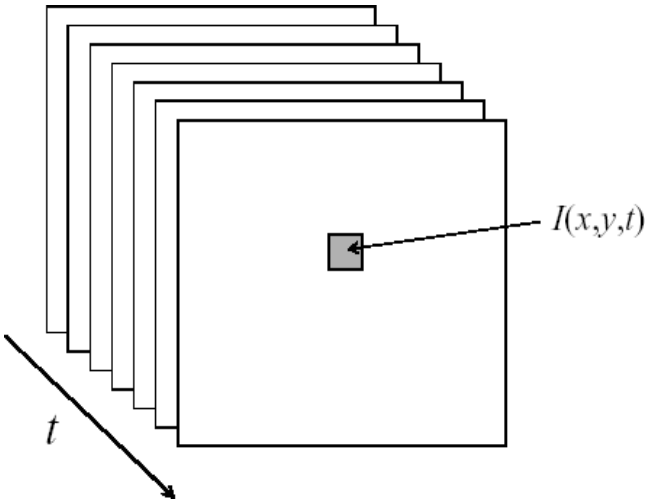
- There are two types of motion to consider:
  - movement in the scene with a static camera,
  - movement of the camera, or ego motion.

Since motion is relative anyway, these types of motion should be the same.

However, this is not always the case, since if the scene moves relative to the illumination, shadow effects need to be dealt with. Also, specularities can cause relative motion within the scene. For this lecture, we will ignore all such complications.

Adapted from Robyn Owens, http://homepages.inf.ed.ac.uk/rbf/CVonline/LOCAL_COPIES/OWENS/LECT12/node3.html

Motion



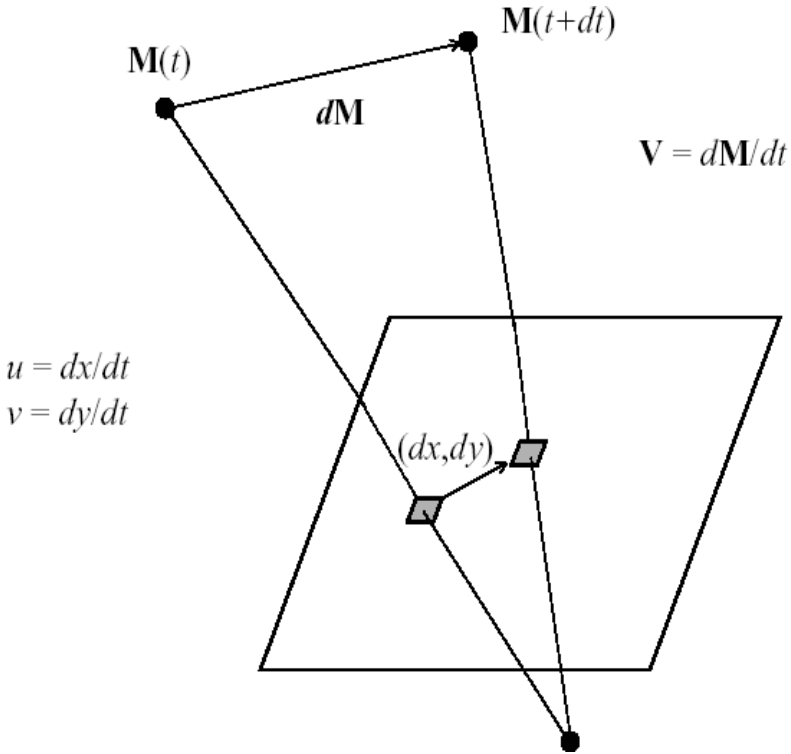
Consider a sequence of images captured over time.

This can be viewed as adding a third dimension, the time *t*, to the image. That is, each pixel is not only a function *I*(*x*,*y*) of the spatial coordinates (*x*,*y*) but also a function *I*(*x*,*y*,*t*) of time.

The main issue in motion analysis is to recover information about the motion in the scene from the variation of the intensities *I*(*x*,*y*,*t*) over time.

Adapted from Martial Hebert, CMU

Motion field



When an object moves in front of a camera, there is a corresponding change in the image

- Given a point in the scene at position **M** at time *t*, the point moves to **M**(*t*+*dt*) after a small interval *dt*.
- The corresponding velocity vector is

  V = *d***M**/*dt*. The points **M**(*t*) and **M**(*t*+*dt*) project at points **m**(*t*) and **m**(*t*+*dt*) in the image.

- If *x*(*t*) and *y*(*t*) are the camera coordinates of **m**(*t*), the apparent velocity in the image has components:

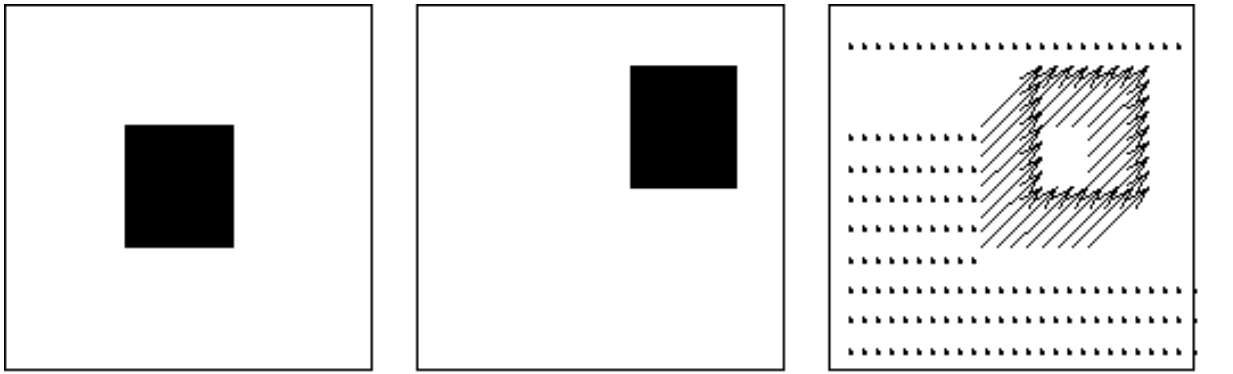
  u = *dx*/*dt* and *v* = *dy*/*dt*

- Motion field is the set of values *u*(*x*,*y*) and *v*(*x*,*y*) over the image

- The problem of motion recovery is then to estimate *u* and *v* at the image pixels

Motion field

- If we are only dealing with rigid body translations and rotations, then the motion field will be continuous except at the silhouette boundaries of objects.



The motion field of a moving square.

Adapted from Robyn Owens, http://homepages.inf.ed.ac.uk/rbf/CVonline/LOCAL_COPIES/OWENS/LECT12/node3.html

Motion field

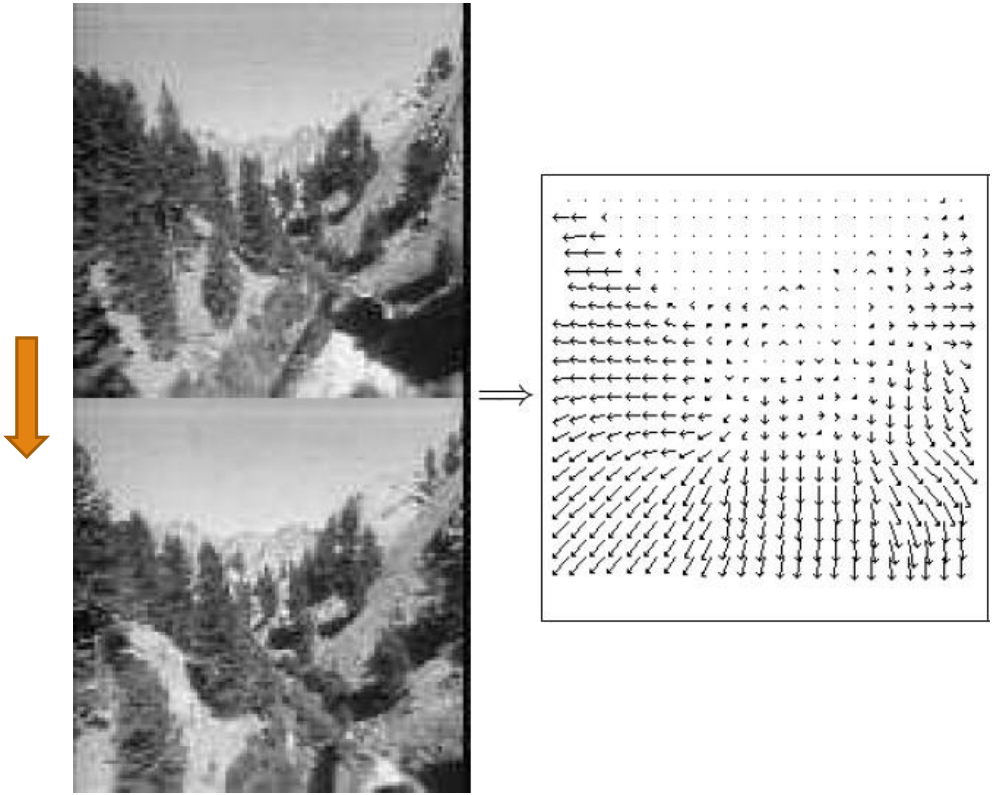
- In the case of pure camera translation, the direction of motion is along the projection ray through that image point from which (or towards which) all motion vectors radiate.

- The point of divergence (or convergence) of all motion field vectors is called the *focus of expansion* FOE (or *focus of contraction* FOC).

Adapted from Robyn Owens, http://homepages.inf.ed.ac.uk/rbf/CVonline/LOCAL_COPIES/OWENS/LECT12/node3.html

Focus of Expansion – for translating camera

- In the case of divergence we have forward motion of the camera



points closer to the camera move more quickly across the Image plane

Adapted from Michael Black

Focus of Contraction – for translating camera

- In the case of convergence, backwards motion.

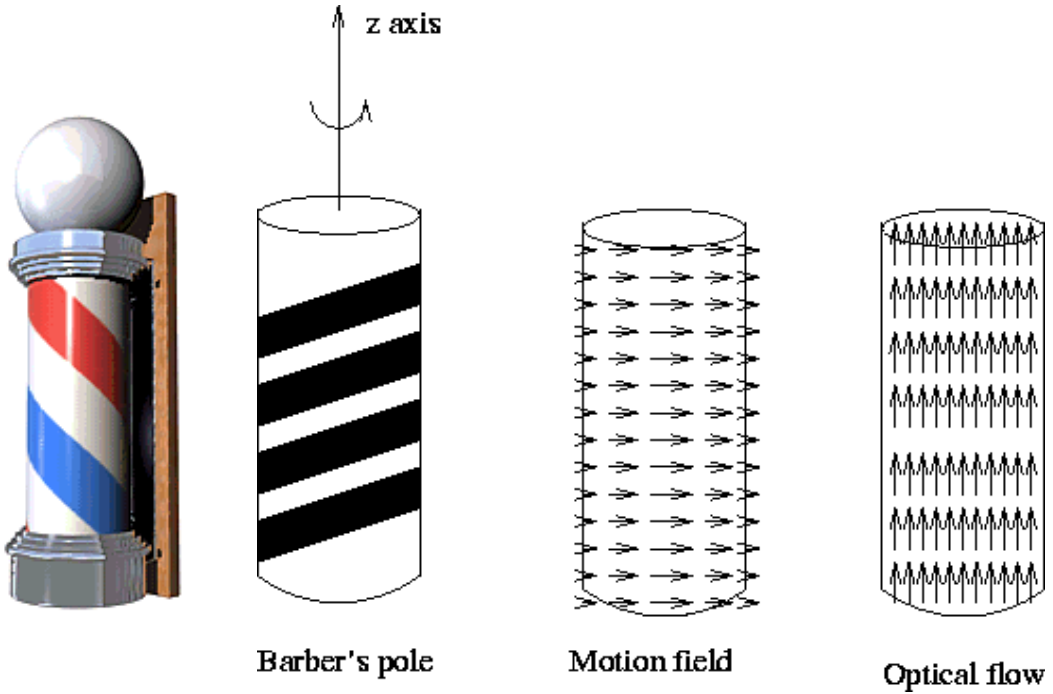
Optical flow

Optical flow is the apparent motion of brightness patterns in the image. Generally, optical flow corresponds to the motion field, **but not always**.

For example, the motion field and optical flow of a rotating barber's pole are different.

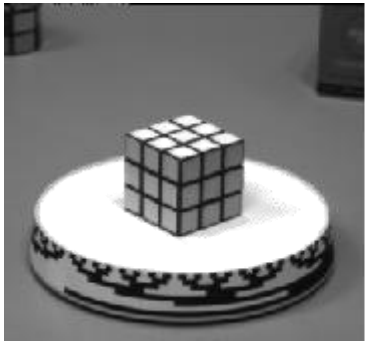
In general, such cases are unusual, and for this lecture we will assume that optical flow corresponds to the motion field.

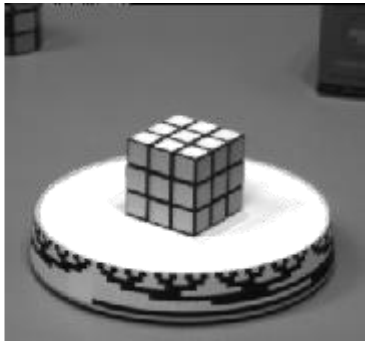


Adapted from Robyn Owens, http://homepages.inf.ed.ac.uk/rbf/CVonline/LOCAL_COPIES/OWENS/LECT12/node3.html

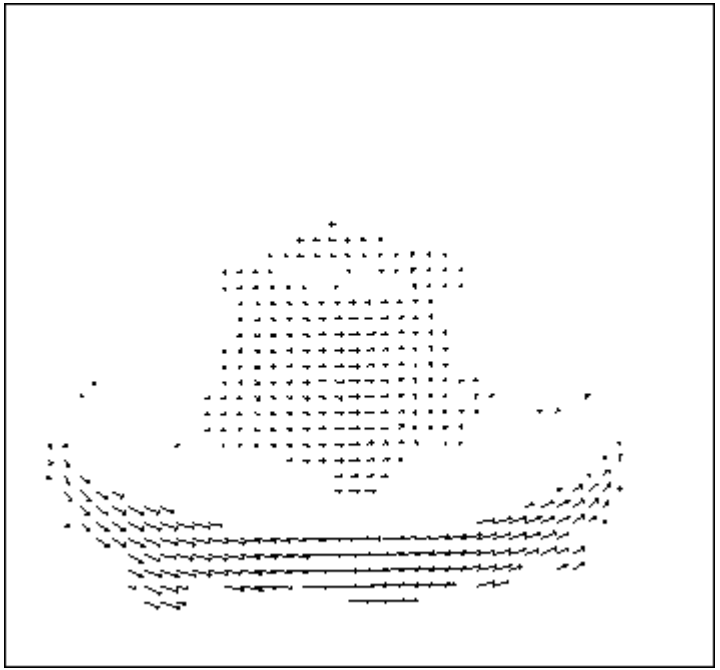
Optical flow

The optical flow describes the direction and the speed of motion of the features in the image.





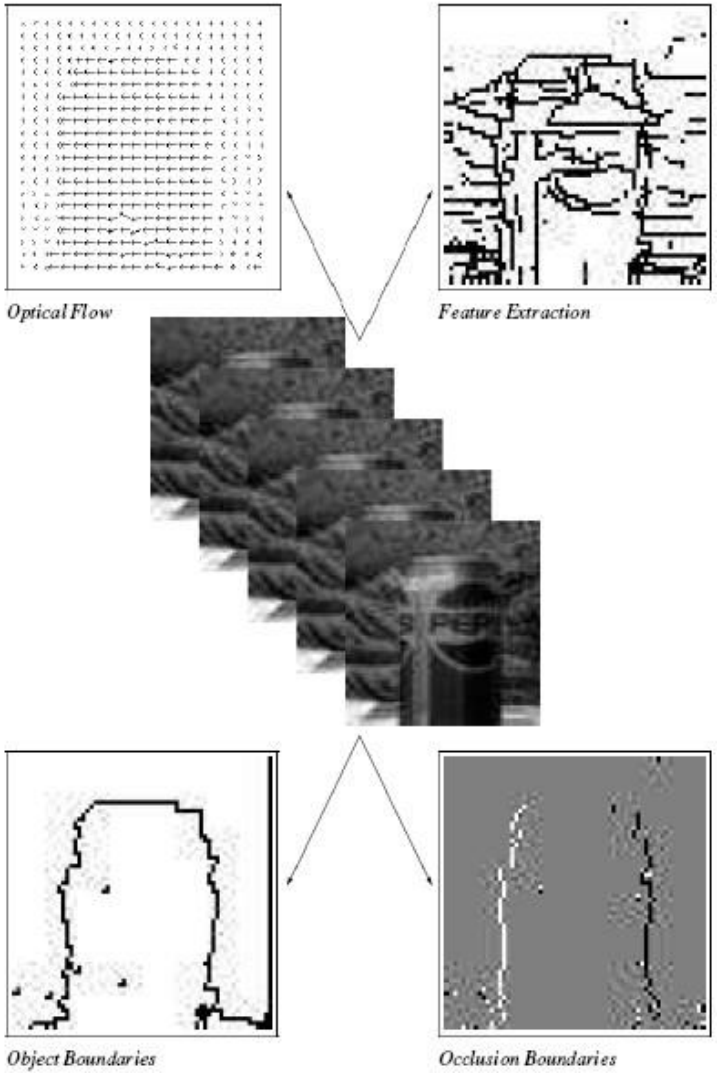
A Rubik's cube on a rotating turntable and Flow vectors calculated from comparing the two images of a Rubik's cube , taken from Russell and Norvig, ``AI, A Modern Approach'', Prentice Hall, 1995,



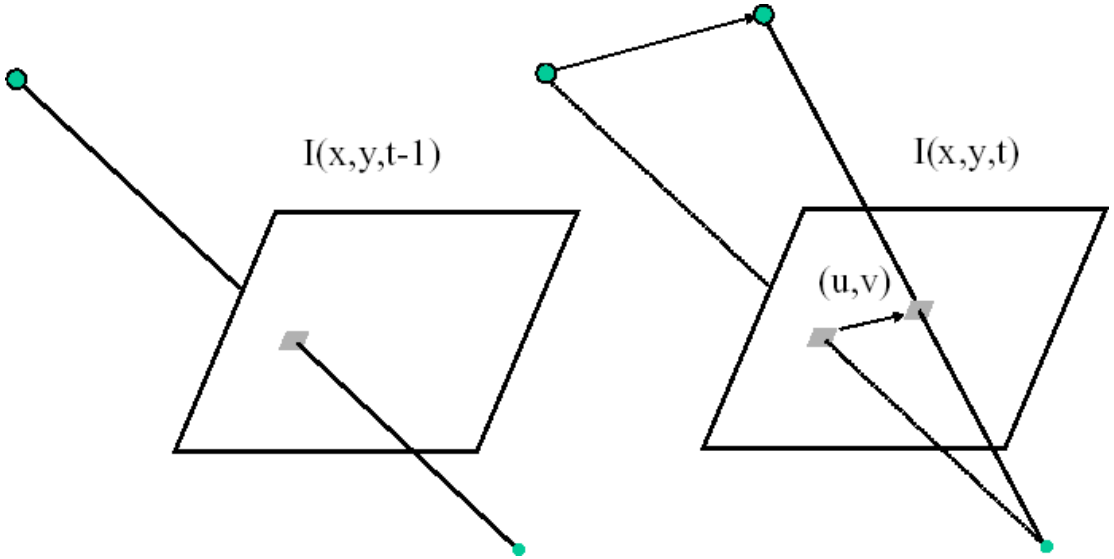
Adapted from http://robotics.eecs.berkeley.edu/~sastry/ee20/vision3/node2.html

Optical flow

- Figure contains two distinct motions:
- The can is moving more rapidly than the background
- This could be used for detecting object boundaries



Optical flow



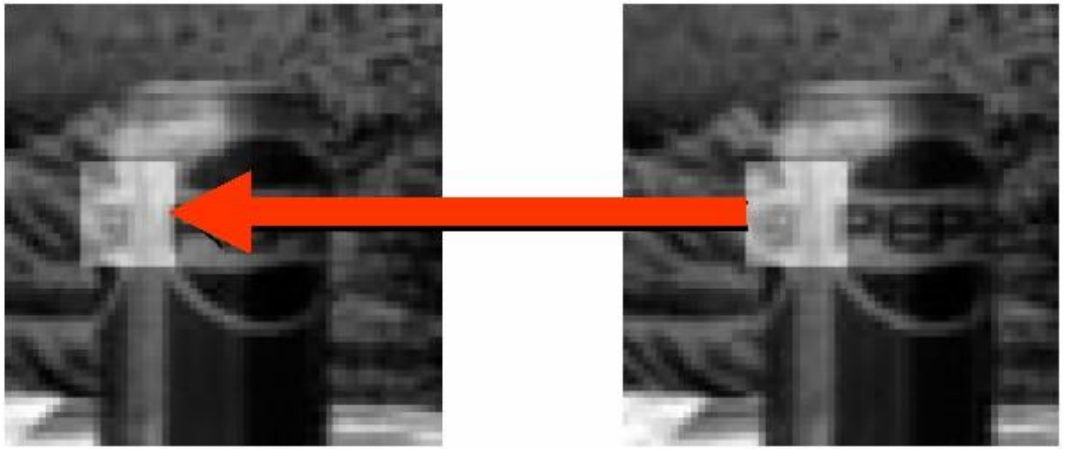
Let’s consider two frames, at time t-1 and time t.

At a given pixel (x,y), the flow components are given by u(x,y) and v(x,y).

At time t, pixel (x,y) has moved to position (x+u(x,y), y+v(x,y)) with intensity I(x+u(x,y), y+v(x,y), t).

Adapted from Martial Hebert, CMU

Brightness Constancy



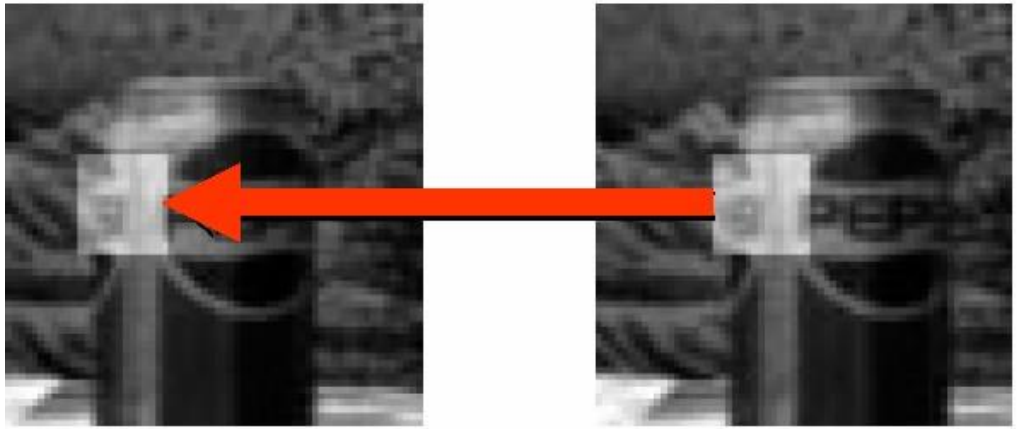
Assumption

Image measurements (e.g. brightness) in a small region remain the same although their location may change.

i.e. the intensity of a scene point does not change over time. This implies that we assume Lambertian sufraces and no change in illumination during the interval dt.

Adapted from Michael Black

Brightness Constancy



$$I(x+u, y+v, t+1) = I(x, y, t)$$

(assumption)

This assumption of *brightness conservation* implies that: assuming that u and v are small, we can use a first order approximation:

$$I(x+u(x,y), y+v(x,y), t+1) = I(x,y,t)$$

Adapted from Michael Black

Optical Flow Equation

Assuming that u and v are small we can make a first-order approximation

$$I(x+u(x,y),y+v(x,y),t) \approx I(x,y,t)+u(x,y)\frac{\partial I}{\partial x}+v(x,y)\frac{\partial I}{\partial y}$$

The two derivatives are the components of the image gradient at (x,y) which are denoted by I_x and I_y.

I_t as the difference: $I_t = I(x,y,t) - I(x,y,t-1)$

Substituting this approximation of $I(x+u(x,y), y+v(x,y), t)$ in the brightness constancy equation, we end up with the fundamental equation of motion:

$$uI_x + vI_y + I_t = 0$$

Adapted from Martial Hebert, CMU

Optical Flow

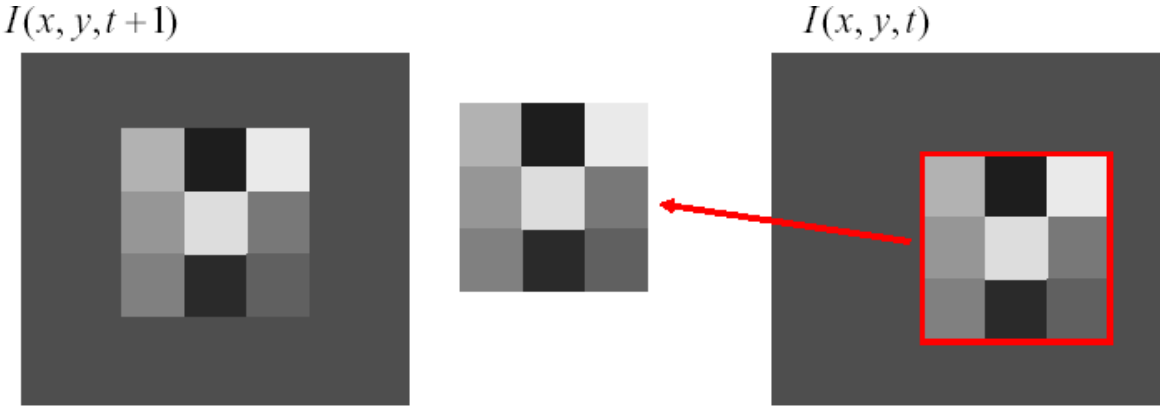
In order to be able to measure optical flow we need to find corresponding points between two frames.

One possibility would be to exploit the similarity between the image patches surrounding the individual points.

Two measures of similarity:
- Sum of squared differences (SSD)
- Cross-correlation

Adapted from http://robotics.eecs.berkeley.edu/~sastry/ee20/vision3/node2.html

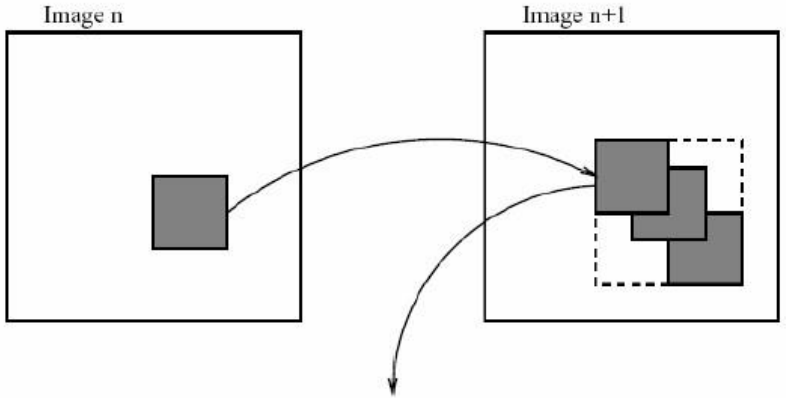
Minimize Brightness difference



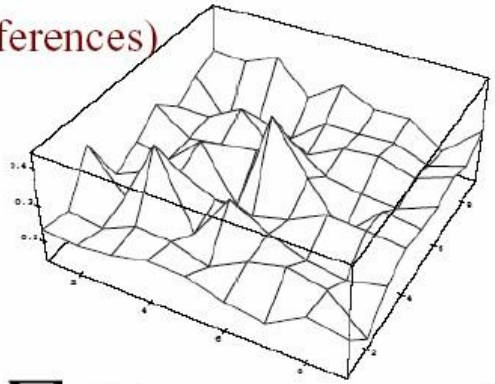
$$E_{SSD}(u,v) = \sum_{x,y \in R} (I(x+u, y+v, t+1) - I(x,y,t))^2$$

Adapted from Michael Black

Minimize Brightness difference



SSD surface
(sum of squared differences)



$$E_{SSD}(u,v) = \sum_{x,y \in R} (I(x+u, y+v, t+1) - I(x,y,t))^2$$

Adapted from Michael Black

Simple SSD algorithm

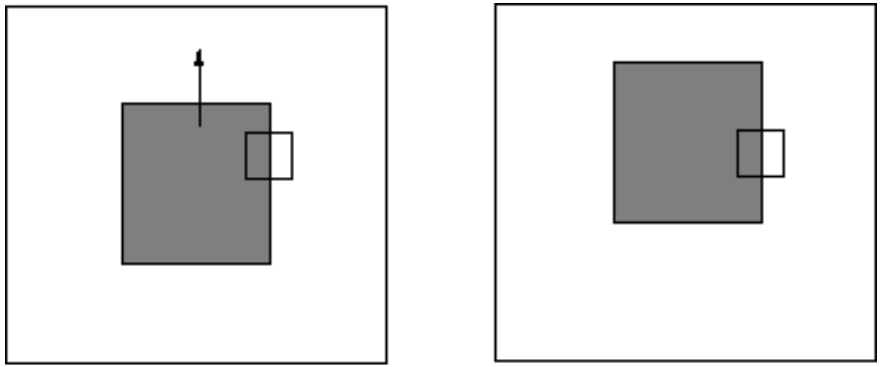
For every pixel (i,j) in the image at t-1
    Cut out a neighborhood of pixels
    For every pixel (k,l) in image at t
        u=k-i; v=l-j;
        Compute the E(u,v)
    End for
    Choose the (u,v) that **minimize** E(u,v)
End for

Problems?

1. not very efficient
2. (u,v) defined on a pixel grid

Adapted from Michael Black

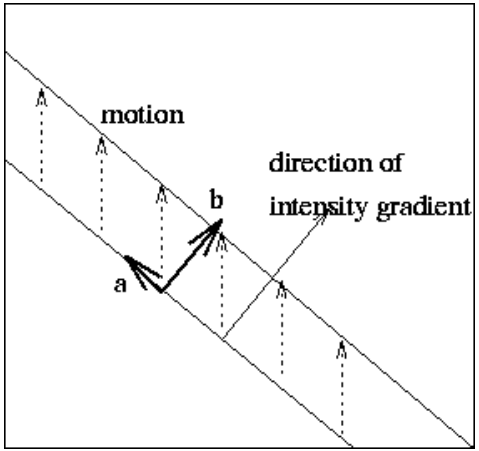
Optical Flow



In spite of the fact that the dark square moved between the two consecutive frames, observing purely the cut-out patch we cannot observe any change, or we may assume that the observed pattern moved arbitrarily along the direction of the edge. The fact that one cannot determine the optical flow along the direction of the brightness pattern is known as *aperture problem.*

Adapted from http://robotics.eecs.berkeley.edu/~sastry/ee20/vision3/node2.html

Aperture Problem



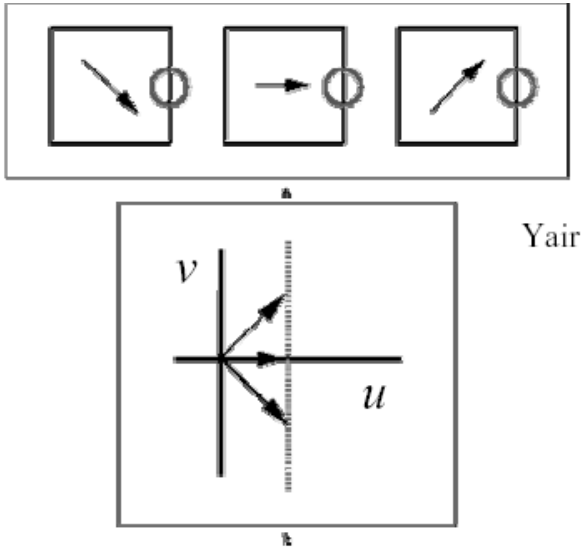
- Consider one point in the image. We are computing the gradient in a small window around this point (the “aperture”).
- Within this small window, the intensity varies in the direction of the gradient, but not in the direction perpendicular to the gradient.
- In terms of edges: the intensity varies across the edge but not along the edge.
- As a result, a motion (*u*,*v*) that is parallel to the edge can never be recovered. In other words, even though the flow has two coordinates, only one of them (in the direction of the gradient) can be recovered.

Adapted from Martial Hebert, CMU

Aperture Problem

$$I_x u + I_y v = -I_t$$
$$I_x u + 0v = -I_t$$
$$I_x u = -I_t$$
$$u = -I_t / I_x$$

v could be anything



Yair Weiss

Adapted from Michael Black

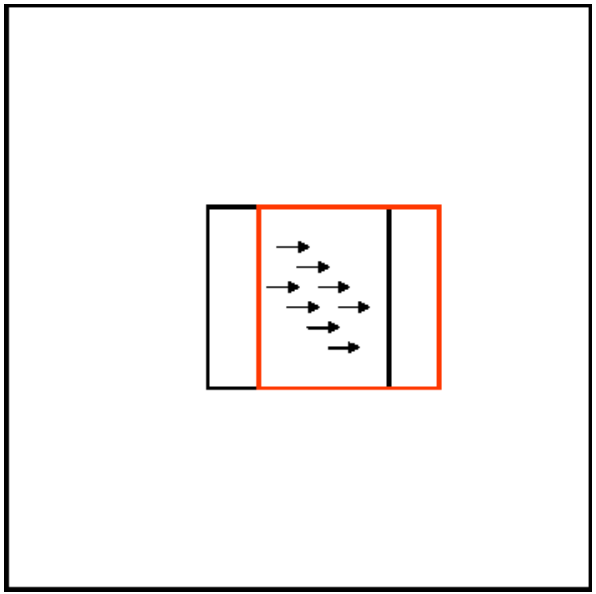
Aperture Problem

- The optical flow equation gives us one constraint per pixel, but we have two unknowns *u* and *v*. Therefore, the flow cannot be recovered unambiguously from this equation alone. The problem is under-constrained.
- Because of the under-constrained nature of the problem. One can solve the optical flow only by adding more constraints to the optical flow equation.

$$I_x u + I_y v = -I_t$$
$$I_x u + 0v = -I_t$$
$$I_x u = -I_t$$
$$u = -I_t / I_x$$

Adapted from Martial Hebert, CMU

Constant flow



Assume that the flow is constant (u,v) over a small region W in the image.

We can express the fact that the optical flow equation is satisfied at every point of W by saying that the function E defined by:

$$E(u,v) = \sum_{(x,y)\in W} \left(uI_x(x,y) + vI_y(x,y) + I_t\right)^2$$

is close to 0. More formally, the constant flow (u,v) most consistent with the intensity values in W is found as:

$$\min_{u,v} E(u,v)$$

Adapted from Martial Hebert, CMU

Constant flow - Lucas-Kanade flow

The minimization can be expressed as a simple least-squares problem:

$$\text{Min}\left\| \mathbf{A}\begin{bmatrix} u \\ v \end{bmatrix} + \mathbf{b} \right\|^2$$

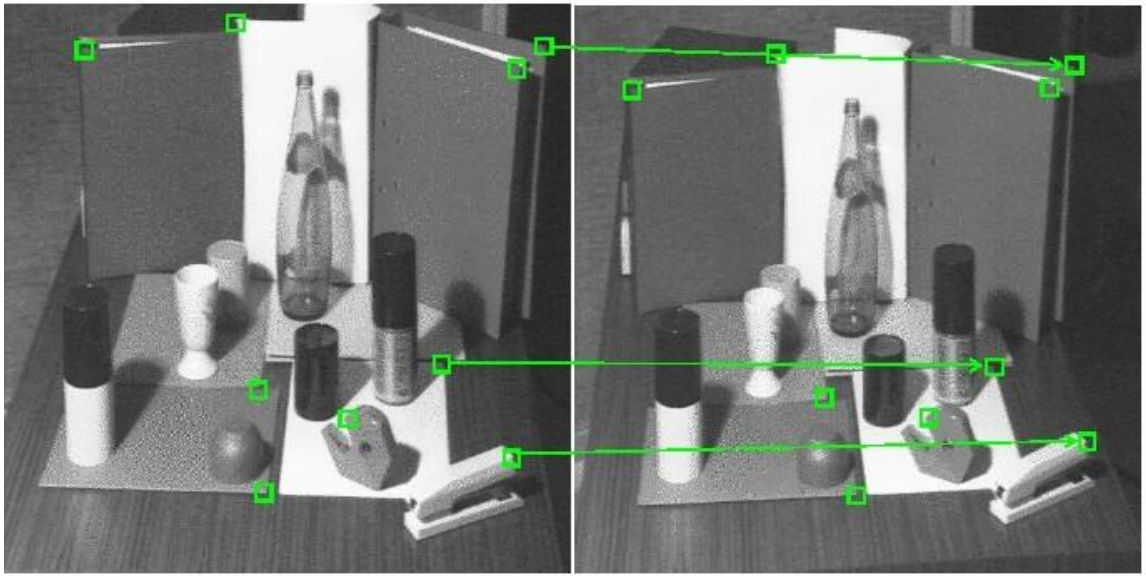
with

$$\mathbf{A} = \begin{bmatrix} I_x(x_o, y_o)\, I_y(x_o, y_o) \\ \vdots \quad\quad \vdots \\ I_x(x_n, y_n)\, I_y(x_n, y_n) \end{bmatrix} \quad \mathbf{b} = \begin{bmatrix} I_t(x_o, y_o) \\ \vdots \\ I_t(x_n, y_n) \end{bmatrix}$$

Therefore, assuming constant flow over a region, motion can be estimated directly by a simple least squares estimation.

Adapted from Martial Hebert, CMU

Feature Tracking



1. Extract features - The features that are most often used are the corner features
2. Track the features from frame to frame. For this, we are going to assume that the frames are spaced closely enough in time that the motion between frames is small.

Adapted from Martial Hebert, CMU

Feature Tracking - Lucas-Kanade flow

Given a feature at location (xo,yo) in one image $I1$, the tracking problem is to basically find the position $(xo+u,yo+v)$ of the corresponding feature in the next image $I2$ in the sequence, where u and v are the components of the motion field at (xo,yo). Let's define a window W around (xo,yo)

The set of pixels inside W in $I1$ is denoted by $W(I1)$. Assuming that the window is not too large, we can assume that the motion field is constant inside W. Therefore, we can use the constant flow algorithm to recover u and v. This is recovered by minimizing in u and v the quantity:

$$E(u,v) = \sum_{(x,y)\in W} \left(uI_x(x,y) + vI_y(x,y) + I_t\right)^2$$

It turns out that the solution is given by:

$$\begin{bmatrix} \sum I_x^2 & \sum I_x I_y \\ \sum I_x I_y & \sum I_y^2 \end{bmatrix} \begin{bmatrix} u \\ v \end{bmatrix} = -\begin{bmatrix} \sum I_x I_t \\ \sum I_y I_t \end{bmatrix}$$

Lucas-Kanade equation

Gauss-Newton approximation of the Hessian

Adapted from Martial Hebert, CMU

Feature Tracking - Lucas-Kanade flow

It turns out that the solution is given by:

$$\begin{bmatrix} \sum I_x^2 & \sum I_x I_y \\ \sum I_x I_y & \sum I_y^2 \end{bmatrix} \begin{bmatrix} u \\ v \end{bmatrix} = -\begin{bmatrix} \sum I_x I_t \\ \sum I_y I_t \end{bmatrix}$$

Gauss-Newton approximation of the Hessian

Remember the least squares solution:

$$\mathbf{p}^* = \left(\sum_i J(\mathbf{x}_i)^\top J(\mathbf{x}_i) \right)^{-1} \sum_i J^\top(\mathbf{x}_i) \Delta \mathbf{x}_i$$

Feature Tracking

$$\begin{bmatrix} \sum I_x^2 & \sum I_x I_y \\ \sum I_x I_y & \sum I_y^2 \end{bmatrix}$$

Remarkably, the matrix involved in this calculation is exactly the same as the matrix used in the corner detector!!

This is not surprising: The matrix characterizes the 2-D distribution of the gradient vectors in *W*, and this relation states that the variation of intensity over time is the product of the motion vector by the gradient distribution.

Note in particular that the matrix is singular when *W* contains an edge (gradient in one direction only) which is exactly when the motion vector cannot be recovered.

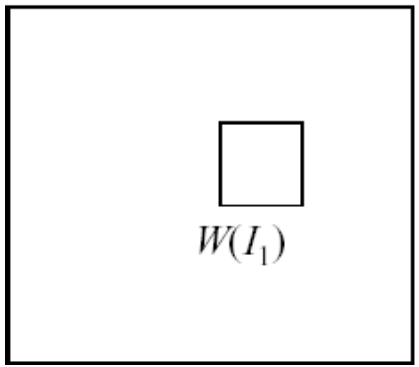
Adapted from Martial Hebert, CMU

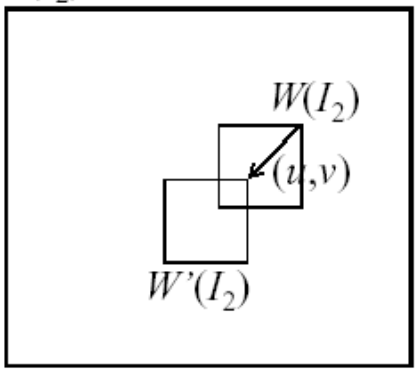
Feature Tracking - Iterative algorithm (Lucas-Kanade)

- Given:
  - Images I_1 and I_2
  - Feature at (x_o,y_o) in I_1
  - Window W at (x_o,y_o)
- Compute displacement in image (u,v):

$$\begin{bmatrix} \sum I_x^2 & \sum I_x I_y \\ \sum I_x I_y & \sum I_y^2 \end{bmatrix} \begin{bmatrix} u \\ v \end{bmatrix} = -\begin{bmatrix} \sum I_x I_t \\ \sum I_y I_t \end{bmatrix}$$

- I_t is the pixel difference between $W(I_1)$ and $W(I_2)$
- Translate W by (u,v) to W'
- Compare $W(I_1)$ and $W'(I_2)$





The algorithm solves for the constant motion inside *W* by inverting the "corner" matrix. This gives the offset (*u*,*v*) to the position in the next image.

At each iteration, the window *W* is shifted by the recovered motion to *W'*. The pixels *W(I1)* and *W'(I2)* are then compared (using SSD for example). If they are too different, that means that the motion *(u,v)* is not quite correct and another iteration of the constant flow is applied, replacing *W* by *W'.* The iterations continue until (*u*,*v*) gets very small or the windows match.

Adapted from Martial Hebert, CMU

Limits of the local gradient method (Lucas-Kanade)

1. Fails when intensity structure within window is poor
2. Fails when the displacement is large (typical operating range is motion of 1 pixel per iteration!)
   - *Linearization of brightness is suitable only for small displacements*

Also, brightness is not strictly constant in images

- *actually less problematic than it appears, since we can pre-filter images to make them look similar*

Adapted from Trevor Darrell, MIT

Feature Tracking

Since we are interested in the motion of the center point (*x*o,*y*o) of *W*, it might be useful to give more weight to the pixels at the center of *W* than to those at the periphery. This is achieved by multiplying the values *I*x(*x*,*y*) and *I*y(*x*,*y*) by a weight *w*(*x*,*y*) which is maximum at the center and tapers off at the edges of *W* (a Gaussian, for example.)

To deal with larger motions, it can be advantageous to first reduce the size of images (after smoothing) and recover the motion at a coarse scale before recovering motion at full resolution. Incidentally, this class of trackers is called the *Lucas-Kanade* tracker.

Adapted from Trevor Darrell, MIT

Iterative Refinement

Iterative Lucas-Kanade Algorithm

1. Estimate velocity at each pixel by solving Lucas-Kanade equations
2. Warp $I1$ towards $I2$ using the estimated flow field
   - *use image warping techniques*
3. Repeat until convergence

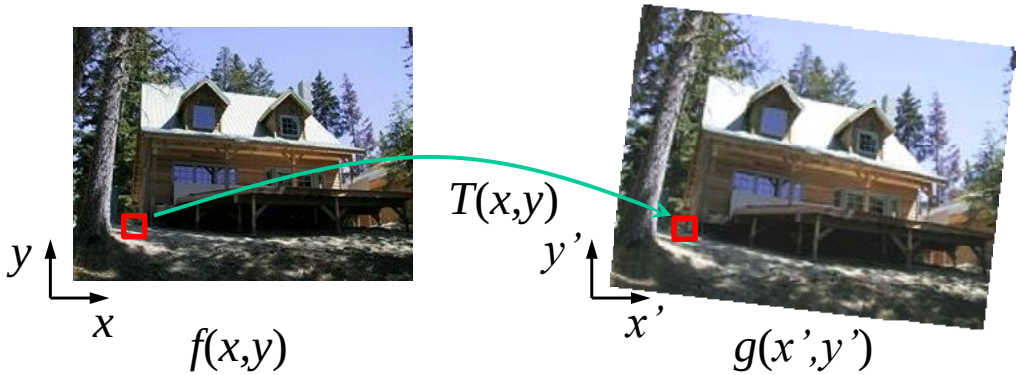
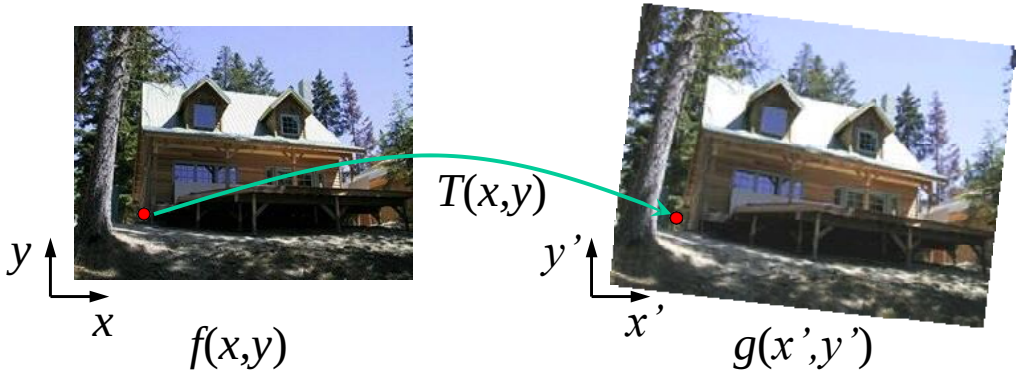
Image warping



Given a coordinate transform *(x',y')* = *h*(*x*,*y*) and a source image *f*(*x*,*y*), how do we compute a transformed image *g(x',y')* = *f*(*T*(*x*,*y*))?

Forward warping

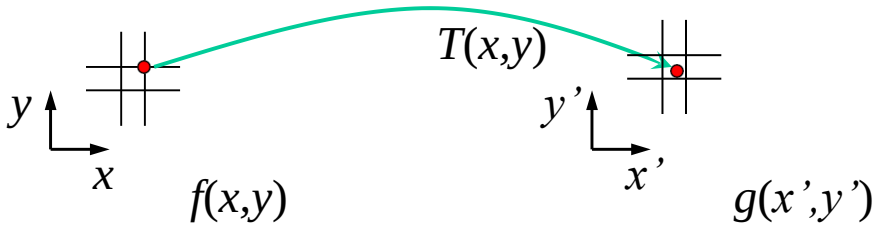


Send each pixel $f(x,y)$ to its corresponding location

$(x',y') = T(x,y)$ in the second image

Q: what if pixel lands “between” two pixels?

Forward warping



Send each pixel $f(x,y)$ to its corresponding location

$(x',y') = T(x,y)$ in the second image

Q: what if pixel lands "between" two pixels?

A: distribute color among neighboring pixels (x',y')

- Known as "splatting"

Visual Tracking

Tracking is the problem of generating an inference about the motion of an object given a sequence of images.

Some of the application areas:

- Motion Capture
- Recognition From Motion
- Human Computer Interaction
- Surveillance
- Targeting

Background Subtraction

It is important to segment the moving objects from the background either when viewing a scene from a fixed camera or after stabilization of the camera motion.

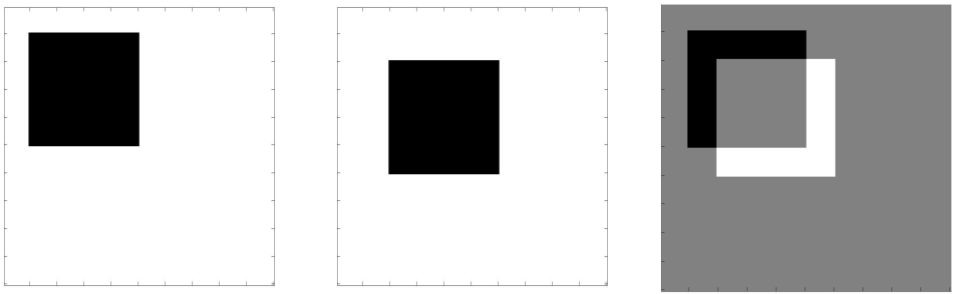
Very important in many applications: surveillance, intelligent rooms, compression (MPEG-7), etc.

$$|I(x,y) - I_b(x,y)| > \tau \; ??$$

Adapted from Martial Hebert, CMU

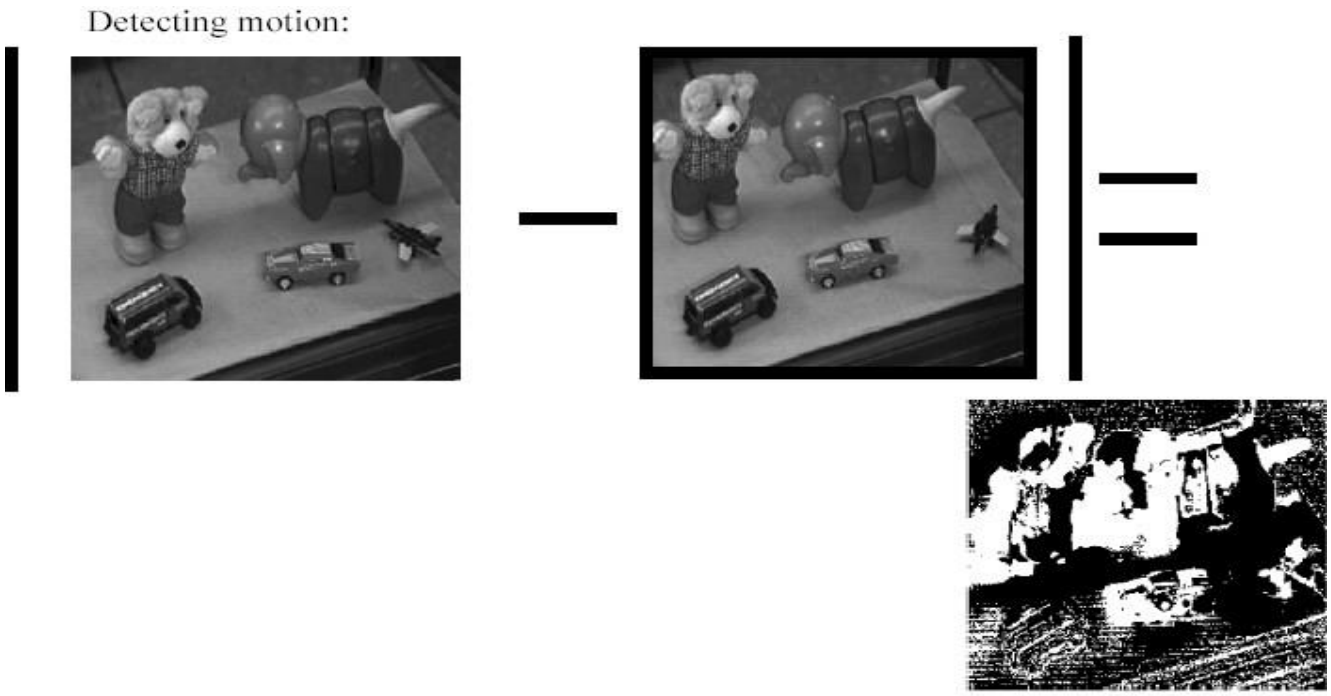
Background Subtraction

- Even simple image differencing provides an edge detector for the silhouettes of texture-free objects moving over any static background.



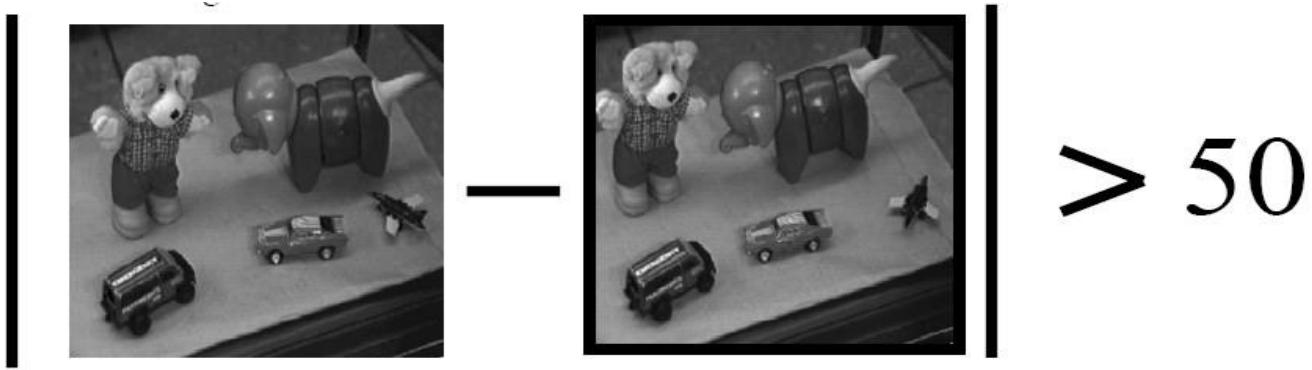
$I(x,y,t)$ $I(x,y,t+1)$ $I(x,y,t+1) - I(x,y,t)$

Motion in real images



Adapted from G. Hager, JHU

Motion in real images



Candidate areas for motion

Adapted from G. Hager, JHU

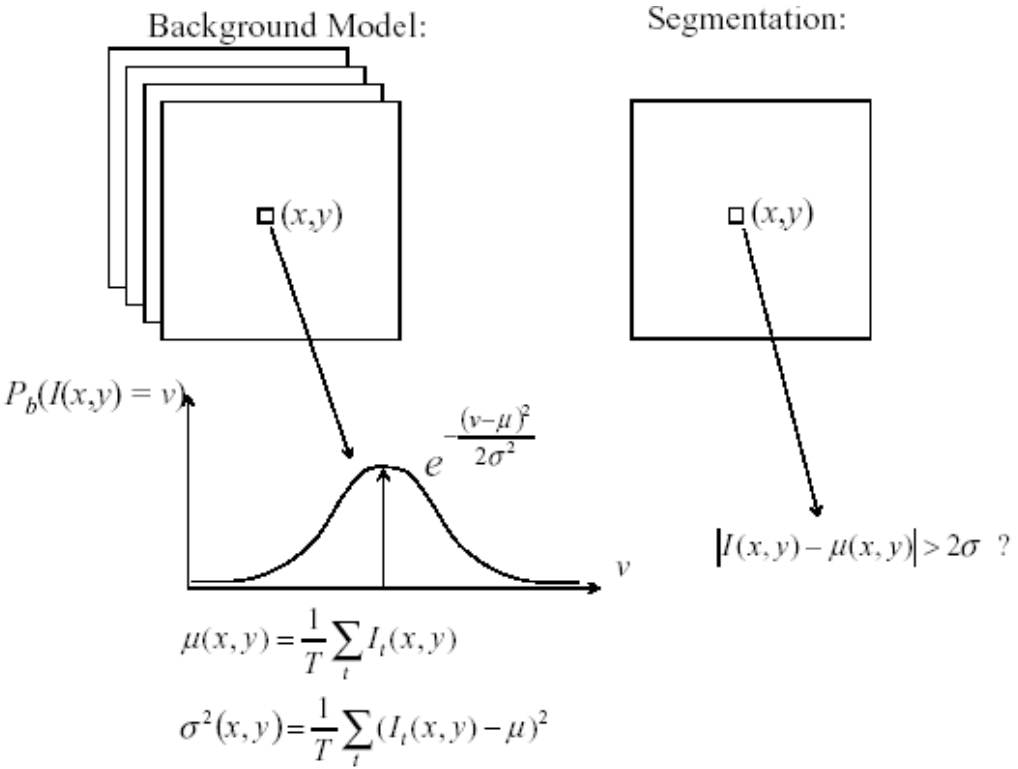
Background Subtraction

The first simple idea would be to identify those pixels that are on moving objects by simply thresholding the difference of intensity $I\mathrm{t}(x,y)$ - $I\mathrm{t}\text{-}1(x,y)$ between the pixel values at times *t* and *t-1*, or to threshold the difference between the current image and the background image $I(x,y)$ - $I\mathrm{g}(x,y)$.

This approach will not work in general because of the key problems in motion segmentation. In particular the changing background: On a pixel by pixel basis, the background is never stationary. The pixel values change constantly due to gradual changes in illumination, and small motion in the environment (for example tree leaves in the wind.)

Adapted from Martial Hebert, CMU

Background Model



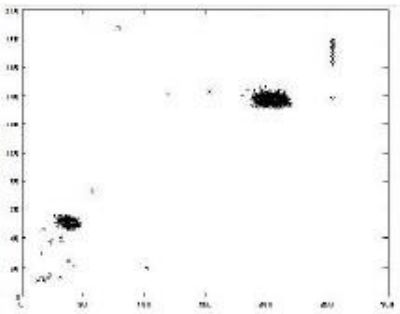
Each pixel is assumed to have a normal (Gaussian) distribution $N(\mu,\sigma)$.

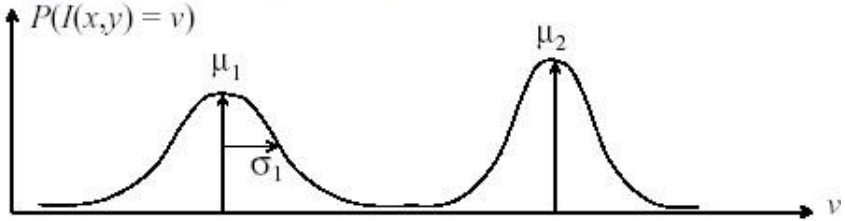
The main problem is that each pixel in the background varies in a different way over time. We need to represent the variation pattern of each pixel as computed from observing sequences of training images from the background. We'll assume for now that we have a set of T images I_t of the background to use for training. We can characterize the variation of each pixel over time by a probability distribution P_b, meaning that $P_b(I(x,y) = v)$ is the probability that pixel (x,y) has value v if it is in the background.

A pixel in the new image is classified as a foreground pixel if $|I(x,y) - \mu| > k\sigma$. k controls the confidence with which we want to detect foreground pixels.

Adapted from Martial Hebert, CMU

Mixture Models





$$P_b(I(x,y)=v)=\sum_i w_i e^{-\frac{(v-\mu_i)^2}{2\sigma_i^2}}$$

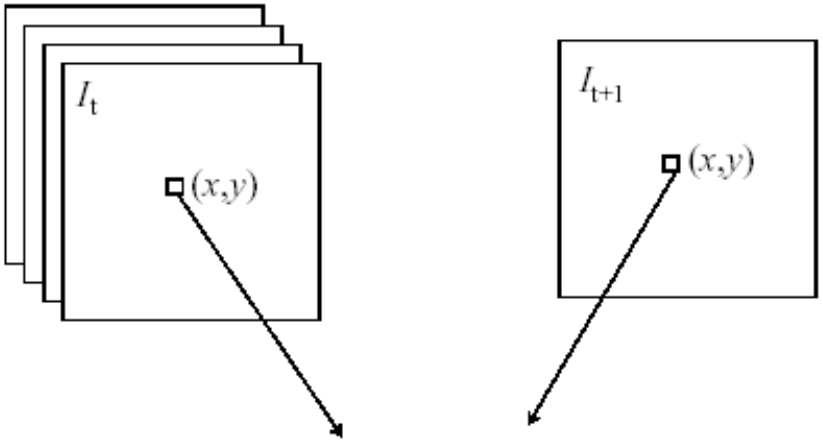
$$P(I(x,y)=v)=\sum_i w_i e^{-\frac{(v-\mu_i)^2}{2\sigma_i^2}}$$

The normal distribution may be too simplistic of a model. Because of small motions in the background scene, a given pixel may be on, for example, three different regions. In that case the sigma of the pixel values may be artificially large and lead to wrong segmentation results. An improved approach is to represent the distribution of each pixel in the background as a weighted sum of normal distributions (called a “mixture of Gaussians”). Each Gaussian is weighted according to the frequency with which it explains the background.

Pixels that are more than two standard deviations away from all the components of the mixture model are classified as foreground pixels.

Adapted from Martial Hebert, CMU

Linear Prediction and Adaptation



model at time t+1 = (1-α) (model at time t) + α (new data)

α = "learning rate"

Gaussian model:

$$\rho = \alpha P_b(v_{t+1})$$
$$\mu_{t+1} = (1-\rho)\mu_t + \rho v_{t+1}$$
$$\sigma^2_{t+1} = (1-\rho)\sigma^2_t + \rho(v_{t+1} - \mu_{t+1})^2$$

The background may change gradually over time, for example, because of gradual changes in lighting. As a result, the model computed from initial training images is no longer valid after observing the scene for some time.

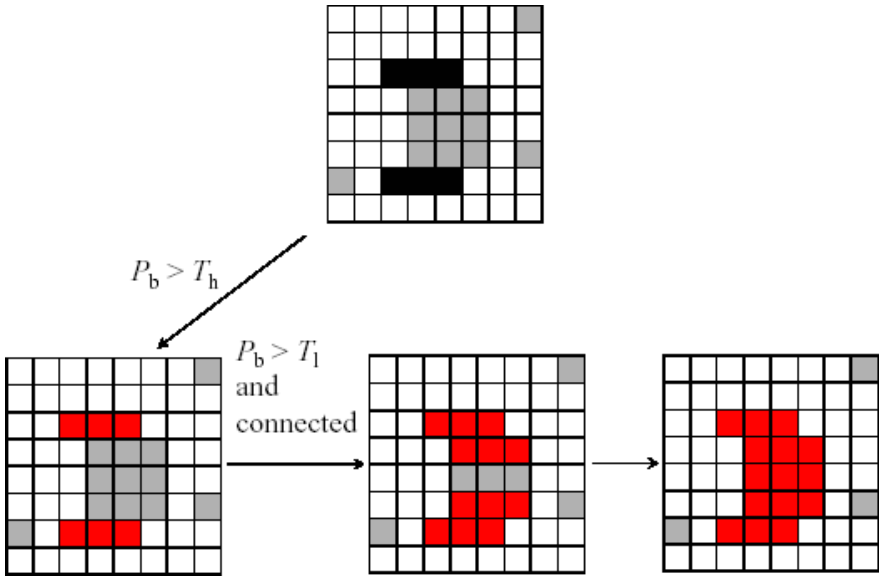
Therefore, the background model needs to be updated over time. In general, a linear update isused, of the form:

model at t+1 = (1-α) (model at t) + α (new data)

α is the learning rate. If α is close to 1, the model is re-created everytime new data arrives; if α is close to 0, the background model changes very slowly over time.

Adapted from Martial Hebert, CMU

Hysteresis Thresholding



Adapted from Martial Hebert, CMU

Moving objects typically form connected regions in the image. The previous techniques tend to generate fragmented regions because some pixels that are part of the moving object may have values that are too close to the background.

Pixels are first classified as foreground using a conservative threshold *T*h. Those pixels are part of foreground objects with high confidence. Then, any pixel that is connected to a foreground pixel and satisfies a less conservative threshold *T*l is also classified as foreground. This approach tends to generate connected regions and to compromise between detection of spurious foreground points and fragmentation of regions.
